

Package ‘dip test’

January 27, 2015

Version 0.75-6
Date 2014-07-29
Title Hartigan's dip test statistic for unimodality - corrected code
Description Compute Hartigan's dip test statistic for unimodality / multimodality and provide a test with simulation based p-values.
Maintainer Martin Maechler <maechler@stat.math.ethz.ch>

dip	<i>Compute Hartigans’ Dip Test Statistic for Unimodality</i>
-----	--

Description
Computes Hartigans’ dip test statistic for testing unimodality, and additionally the modal interval.

Usage

```
dip(x, full.result = FALSE, min.is.0 = FALSE, debug = FALSE)
```

Arguments

<code>x</code>	numeric; the data.
<code>full.result</code>	logical or string; <code>dip(., full.result=TRUE)</code> returns the full result list; if "all" it additionally uses the <code>mn</code> and <code>mj</code> components to compute the initial GCM and LCM, see below.
<code>min.is.0</code>	logical indicating if the minimal value of the dip statistic D_n can be zero or not. Arguably should be set to TRUE for internal consistency reasons, but is false by default both for continuity and backwards compatibility reasons, see the examples below.
<code>debug</code>	logical; if true, some tracing information is printed (from the C routine).

Value

depending on `full.result` either a number, the dip statistic, or an object of class "dip" which is a [list](#) with components

<code>x</code>	the sorted unname() d data.
<code>n</code>	<code>length(x)</code> .
<code>dip</code>	the dip statistic
<code>lo.hi</code>	indices into <code>x</code> for lower and higher end of modal interval
<code>xl, xu</code>	lower and upper end of modal interval
<code>gcm, lcm</code>	(last used) indices for g reatest c onvex m inorant and the l east c oncave m ajorant.
<code>mn, mj</code>	index vectors of length <code>n</code> for the GC minorant and the LC majorant respectively.

For "full" results of class "dip", there are [print](#) and [plot](#) methods, the latter with its own [manual page](#).

Note

For $n \leq 3$ where $n <- \text{length}(x)$, the dip statistic D_n is always the same minimum value, $1/(2n)$, i.e., there's no possible dip test. Note that up to May 2011, from Hartigan's original Fortran code, D_n was set to zero, when all `x` values were identical. However, this entailed discontinuous behavior, where for arbitrarily close data \tilde{x} , $D_n(\tilde{x}) = \frac{1}{2n}$.

Yong Lu <lyongu+@cs.cmu.edu> found in Oct 2003 that the code was not giving symmetric results for mirrored data (and was giving results of almost 1, and then found the reason, a misplaced '"') in the original Fortran code. This bug has been corrected for diptest version 0.25-0.

Nick Cox (Durham Univ.) said (on March 20, 2008 on the Stata-list):

As it comes from a bimodal husband-wife collaboration, the name perhaps should be "*Hartigan-Hartigan dip test*", but that does not seem to have caught on. Some of my less statistical colleagues would sniff out the hegemony of patriarchy there, although which Hartigan is being overlooked is not clear.

Martin Maechler, as a Swiss, and politician, would say:
 Let's find a compromise, and call it “*Hartigans' dip test*”, so we only have to adapt orthography
 (:-).

[dip.test](#) to compute the dip *and* perform the unimodality test, based on P-values, interpolated from [qDiptab](#); [isoreg](#) for isotonic regression.

Examples

```
data(statfaculty)
plot(density(statfaculty))
rug(statfaculty, col="midnight blue"); abline(h=0, col="gray")
dip(statfaculty)
(dS <- dip(statfaculty, full = TRUE, debug = TRUE))
plot(dS)
## even more output -- + plot showing "global" GCM/LCM:
(dS2 <- dip(statfaculty, full = "all", debug = 3))
plot(dS2)

data(faithful)
fE <- faithful$eruptions
plot(density(fE))
rug(fE, col="midnight blue"); abline(h=0, col="gray")
dip(fE, debug = 2) ## showing internal work
(dE <- dip(fE, full = TRUE)) ## note the print method
plot(dE, do.points=FALSE)

data(precip)
plot(density(precip))
rug(precip, col="midnight blue"); abline(h=0, col="gray")
str(dip(precip, full = TRUE, debug = TRUE))

##----- The 'min.is.0' option : -----
##' dip(.) continuity and 'min.is.0' exploration:
```

```

dd <- function(x, debug=FALSE) {
  x_ <- x ; x_[1] <- 0.9999999999 * x[1]
  rbind(dip(x , debug=debug),
        dip(x_, debug=debug),
        dip(x , min.is.0=TRUE, debug=debug),
        dip(x_, min.is.0=TRUE, debug=debug), deparse.level=2)
}

dd( rep(1, 8) ) # the 3rd one differs ==> min.is.0=TRUE is *dis*continuous
dd( 1:7 )      # ditto

dd( 1:7, debug=TRUE)
## border-line case ..
dd( 1:2, debug=TRUE)

## Demonstrate that 'min.is.0 = TRUE' does not change the typical result:
B.sim <- 1000 # or larger
D5 <- {set.seed(1); replicate(B.sim, dip(runif(5)))}
D5. <- {set.seed(1); replicate(B.sim, dip(runif(5), min.is.0=TRUE))}
stopifnot(identical(D5, D5.), all.equal(min(D5), 1/(2*5)))
hist(D5, 64); rug(D5)

D8 <- {set.seed(7); replicate(B.sim, dip(runif(8)))}
D8. <- {set.seed(7); replicate(B.sim, dip(runif(8), min.is.0=TRUE))}
stopifnot(identical(D8, D8.))

```

dip.test

*Hartigans' Dip Test for Unimodality***Description**

Compute Hartigans' dip statistic D_n , and its P-value for the test for unimodality, by interpolating tabulated quantiles of $\sqrt{n}D_n$.

For $X_i \sim F, i.i.d.$, the null hypothesis is that F is a unimodal distribution. Consequently, the test alternative is non-unimodal, i.e., at least bimodal. Using the language of medical testing, you would call the test "Test for **Multimodality**".

Usage

```
dip.test(x, simulate.p.value = FALSE, B = 2000)
```

Arguments

x numeric vector; sample to be tested for unimodality.

simulate.p.value a logical indicating whether to compute p-values by Monte Carlo simulation.

B an integer specifying the number of replicates used in the Monte Carlo test.

Details

If `simulate.p.value` is FALSE, the p-value is computed via linear interpolation (of $\sqrt{n}D_n$) in the [qDiptab](#) table. Otherwise the p-value is computed from a Monte Carlo simulation of a uniform distribution (`runif(n)`) with B replicates.

Value

A list with class "htest" containing the following components:

statistic	the dip statistic D_n , i.e., dip(x) .
p.value	the p-value for the test, see details.
method	character string describing the test, and whether Monte Carlo simulation was used.
data.name	a character string giving the name(s) of the data.

Note

see also the package vignette, which describes the procedure in more details.

Author(s)

Martin Maechler

References

see those in [dip](#).

See Also

For goodness-of-fit testing, notably of continuous distributions, [ks.test](#).

Examples

```
## a first non-trivial case
(d.t <- dip.test(c(0,0, 1,1))) # "perfect bi-modal for n=4" --> P-value = 0
stopifnot(d.t$p.value == 0)

data(statfaculty)
plot(density(statfaculty)); rug(statfaculty)
(d.t <- dip.test(statfaculty))

x <- c(rnorm(50), rnorm(50) + 3)
plot(density(x)); rug(x)
## border-line bi-modal ... BUT (most of the times) not significantly:
dip.test(x)
dip.test(x, simulate=TRUE, B=5000)

## really large n -- get a message
dip.test(runif(4e5))
```

exHartigan

*Hartigan's Artificial n-modal Example Data Set***Description**

63 (integer) numbers; unimodal or bimodal, that's the question.

This is now *deprecated*. Please use [statfaculty](#) instead!

Examples

```
data(exHartigan)
plot(dH <- density(exHartigan))
rug(exHartigan)# should jitter
```

plot.dip

*Plot a dip() Result, i.e., Class "dip" Object***Description**

Plot method for "dip" objects, i.e., the result of [dip](#)(., full.result=TRUE) or similar.

Note: We may decide to enhance the plot in the future, possibly not entirely back-compatibly.

Usage

```
## S3 method for class 'dip'
plot(x, do.points = (n < 20),
      colG = "red3", colL = "blue3", colM = "forest green",
      col.points = par("col"), col.hor = col.points,
      doModal = TRUE, doLegend = TRUE, ...)
```

Arguments

x	an R object of class "dip", i.e., typically the result of dip (., full.result= FF) where FF is TRUE or a string such as "all".
do.points	logical indicating if the ECDF plot should include points; passed to plot.ecdf .
colG, colL, colM	the colors to be used in the graphics for the G reatest convex minorant, the L east concave majorant, and the M odal interval, respectively.
col.points, col.hor	the color of points or horizontal lines, respectively, simply passed to plot.ecdf .
doModal	logical indicating if the modal interval $[x_L, x_U]$ should be shown.
doLegend	logical indicating if a legend should be shown.
...	further optional arguments, passed to plot.ecdf .

See Also[dip](#), also for examples; [plot.ecdf](#).

qDiptab

*Table of Quantiles from a Large Simulation for Hartigan's Dip Test***Description**

Whereas Hartigan(1985) published a table of empirical percentage points of the dip statistic (see [dip](#)) based on $N=9999$ samples of size n from $U[0, 1]$, our table of empirical quantiles is currently based on $N=1'000'001$ samples for each n .

Format

A numeric matrix where each row corresponds to sample size n , and each column to a probability (percentage) in $[0, 1]$. The dimnames are named `n` and `Pr` and coercable to these values, see the examples. `attr(qDiptab, "N_1")` is $N-1$, such that with `k <- as.numeric(dimnames(qDiptab)$Pr) * attr(qDiptab, "e.g., qDiptab[n == 15,]` contains exactly the order statistics $D_{[k]}$ (from the $N+1$ simulated values of [dip](#)(U), where `U <- runif(15)`).

Note

Taking $N=1'000'001$ ensures that all the [quantile](#)(X , p) used here are exactly order statistics `sort(X)[k]`.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>

See Also

[dip](#), also for the references; [dip.test\(\)](#) which performs the hypothesis test, using `qDiptab` (and its null hypothesis of a uniform distribution).

Examples

```
data(qDiptab)
str(qDiptab)
## the sample sizes `n` :
dnqd <- dimnames(qDiptab)
(nn <- as.integer(dnqd $n))
## the probabilities:
P.p <- as.numeric(print(dnqd $ Pr))
```

```
## This is as "Table 1" in Hartigan & Hartigan (1985) -- but more accurate
ps <- c(1,5,10,50,90,95,99, 99.5, 99.9)/100
tab1 <- qDiptab[nn <= 200, as.character(ps)]
round(tab1, 4)
```

statfaculty

Faculty Quality in Statistics Departments

Description

Faculty quality in statistics departments was assessed as part of a larger study reported by Scully(1982). Accidentally, this is also provided as the exHartigan (“**example of Hartigans**”) data set.

Usage

```
data(statfaculty)
```

Format

A numeric vector of 63 (integer) numbers, sorted increasingly, as reported by the reference.

References

J. A. Hartigan and P. M. Hartigan (1985) The Dip Test of Unimodality; *Annals of Statistics* **13**, 70–84.

Examples

```
data(statfaculty)
plot(dH <- density(statfaculty))
rug(jitter(statfaculty))

data(exHartigan)
stopifnot(identical(exHartigan, statfaculty))
```
